

Required Attribute

The `required` attribute is used on a field elements to indicate that a field **must be filled out before form submission**. It is a **Boolean Expression attribute**, meaning that if it's present on an input element and evaluates to true, the field is considered mandatory.

Key Behavior

- Applies to `Entity Attribute`, `Field Element`.
- Prevents form submission if the field is empty or has no valid value.
- Triggers the browser's built-in validation UI (e.g., message saying "Please fill out this field").
- Does **not** override `readonly`, those fields are ignored during validation.

Important: If `required` is set on the **entity attribute**, the layout field **cannot override and revoke** it. This ensures that data integrity rules at the model level are always enforced, regardless of UI configuration.

Conditional

Required is of type `Boolean Expression` which means that it can be either static `true` or `false`, or conditional. See [Conditional Syntax](#) for details.

Required Attributes in Assistants

By default, a field marked as **required** in an assistant will appear as mandatory in the UI, but it will **not** enforce that a value must be entered unless validation is explicitly enabled.

In the legacy design of Assistants, step validation was manually defined on the **Next** and **Finish** commands. Later, a generic framework-based validation mechanism was introduced. When **Step Validation** is enabled, the framework automatically evaluates required fields and field-level validations, and accordingly controls the **Next** and **Finish** buttons.

Due to backward compatibility constraints, this option cannot be enabled by default for all existing assistants. Therefore, developers must explicitly enable **Step Validation** to activate this behavior.

Step Validation - This is an optional attribute on the **Assistant** element.

To enable it:

1. In Page Designer on the assistant element, click (...) to toggle optional attributes visible.
2. Set `Step Validation` to 'Enabled'

Important: For the same reason that **Step Validation** cannot be enabled by default, you should not assume that enabling it will work seamlessly with existing assistants. In some cases, it may not be possible to add a required custom attribute or mark a standard field as required in an existing assistant. This is a known design limitation.
